

EXTRA QUESTIONS

CIRCLES

If two intersecting chords of a circle make equal angles with the diameter passing through their point of intersection, prove that the chords are equal.

**Solution :**

**Given :** AB and CD are two chords of a circle, with centre O intersecting at a point E.  
PQ is a diameter through E, such that  $\angle AEQ = \angle DEQ$

**To prove:** AB = CD.

**Construction:** Draw perpendiculars OL and OM on chords AB and CD respectively.

**Proof:**

$$\begin{aligned}\angle LOE &= 180^\circ - 90^\circ - \angle LEO \\ &= 90^\circ - \angle LEO \text{ (Angle sum property of a triangle)} \\ &= 90^\circ - \angle AEQ = 90^\circ - \angle DEQ \\ &= 90^\circ - \angle MEO = \angle MOE\end{aligned}$$

In triangles OLE and OME,

$$\angle LEO = \angle MEO \quad (\text{Why ?})$$

$$\angle LOE = \angle MOE \quad \text{EO} \quad (\text{Proved above})$$

$$= \text{EO} \quad (\text{Common})$$

Therefore,  $\triangle OLE \cong \triangle OME$  (Why ?)

This gives  $OL = OM$  (CPCT)

So,  $AB = CD$  (Why ?)

AB is a diameter of the circle, CD is a chord equal to the radius of the circle. AC and BD when extended intersect at a point E. Prove that  $\angle AEB = 60^\circ$ .

Solution :

Join OC, OD and BC.

- Triangle ODC is equilateral (Why?) Therefore,  $\angle COD = 60^\circ$
  - Now,  $\angle CBD = \frac{1}{2} \angle COD$  Reason This gives  $\angle CBD = 30^\circ$
  - Again,  $\angle ACB = 90^\circ$  (Why ?)
- So,  $\angle BCE = 180^\circ - \angle ACB = 90^\circ$
- Which gives  $\angle CEB = 180 - (90^\circ + 30^\circ) = 60^\circ$ ,
  - i.e.  $\angle AEB = 60^\circ$

ABCD is a cyclic quadrilateral in which AC and BD are its diagonals. If  $\angle DBC = 55^\circ$  and  $\angle BAC = 45^\circ$ , find  $\angle BCD$ .

Solution :

Given  $\angle CAD = \angle DBC = 55^\circ$  (Angles in the same segment)

Therefore,  $\angle DAB = \angle CAD + \angle BAC$   
 $= 55^\circ + 45^\circ = 100^\circ$

But  $\angle DAB + \angle BCD = 180^\circ$   
(Opposite angles of a cyclic quadrilateral)  
So,  $\angle BCD = 180^\circ - 100^\circ = 80^\circ$

Prove that the quadrilateral formed (if possible) by the internal angle bisectors of any quadrilateral is cyclic.

Solution :

ABCD is a quadrilateral in which the angle bisectors AH, BF, CF and DH of internal angles A, B, C and D respectively form a quadrilateral EFGH.

Now,

$$\begin{aligned}\angle FEH &= \angle AEB = 180^\circ - \angle EAB - \angle EBA \text{ (Why?)} \\ &= 180^\circ - 1/2(\angle A + \angle B)\end{aligned}$$

and

$$\begin{aligned}\angle FGH &= \angle CGD = 180^\circ - \angle GCD - \angle GDC \text{ (Why?)} \\ &= 180^\circ - 1/2(\angle C + \angle D)\end{aligned}$$

$$\begin{aligned}\text{Therefore, } \angle FEH + \angle FGH &= 180^\circ - 1/2(\angle A + \angle B) + 180^\circ - 1/2(\angle C + \angle D) \\ &= 360^\circ - 1/2(\angle A + \angle B + \angle C + \angle D) \\ &= 360^\circ - 1/2 \times 360^\circ \\ &= 360^\circ - 180^\circ = 180^\circ\end{aligned}$$

Therefore quadrilateral EFGH is cyclic **REASON**

Two chords AB and CD of lengths 5 cm and 11 respectively of a circle are parallel to each other and are on opposite sides of its centre. If the distance between AB and CD is 6 cm, find the radius of the circle.

Sol.

Let O be the centre of the given circle and let its radius be  $r$  cm. Draw  $OP \perp AB$  and  $OQ \perp CD$ . Since  $OP \perp AB$ ,  $OQ \perp CD$  and  $AB \parallel CD$ . Therefore, points P, O and Q are collinear. So  $PQ = 6$  cm.

Let  $OP = x$ . Then,  $OQ = (6 - x)$  cm. Join OA and OC. Then,  $OA = OC = r$ .

Since the perpendicular from the centre to a chord of the circle bisects the chord.

Therefore  $AP = PB = 2.5$  cm and  $CQ = QD = 5.5$  cm. In

right  $\Delta$ s OAP and OCQ, we have

$$OA^2 = OP^2 + AP^2 \text{ and } OC^2 = OQ^2 + CQ^2$$

$$\Rightarrow r^2 = x^2 + (2.5)^2 \dots\dots\dots (1)$$

$$\text{and } r^2 = (6-x)^2 + (5.5)^2 \dots\dots\dots (2)$$

$$\Rightarrow x^2 + (2.5)^2 = (6-x)^2 + (5.5)^2 \Rightarrow x^2 + 6.25 = 36 - 12x + x^2 + 30.25$$

$$\Rightarrow 12x = 60 \Rightarrow x = 5$$

Putting  $x = 5$  in (1), we get

$$r^2 = 5^2 + (2.5)^2 = 25 + 6.25 = 31.25$$

$$\Rightarrow r = \sqrt{31.25} = 5.6 \text{ (approx.)}$$

Hence, the radius of the circle is 5.6 cm (approx.)

The lengths of two parallel chords of a circle are 6 cm and 8 cm. If the smaller chord is at distance 4 cm from the centre, what is the distance of the other chord from the centre.

Sol.

Let AB and CD be two parallel chords of a circle with centre O such that AB = 6 cm and CD = 8 cm.

Let the radius of the circle be r cm.

Draw  $OP \perp AB$  and  $OQ \perp CD$ . Since  $AB \parallel CD$  and  $OP \perp AB$ ,  $OQ \perp CD$ . Therefore, points O, Q and P are collinear. Clearly  $OP = 4$  cm, and P, Q are mid-points of AB and CD respectively.

Therefore  $AP = PB = \frac{1}{2}(AB) = 3$  cm

and,  $CQ = QD = \frac{1}{2}(CD) = 4$  cm

In rt.  $\triangle OAP$ , we have

$$OA^2 = OP^2 + AP^2$$

$$\Rightarrow r^2 = 4^2 + 3^2 = 16 + 9 = 25$$

$$\Rightarrow r = 5$$

In rt.  $\triangle OCQ$ , we have

$$OC^2 = OQ^2 + CQ^2$$

$$\Rightarrow r^2 = OQ^2 + 4^2$$

$$\Rightarrow 25 = OQ^2 + 16$$

$$\Rightarrow OQ^2 = 9$$

$$\Rightarrow OQ = 3$$

Hence, the distance of chord CD from the centre is 3 cm.

ABCD is a parallelogram. The circle through A, B and C intersect CD (produced if necessary) at E. Prove that  $AE = AD$ .

To prove:  $AE = AD$

( $\Delta AED$  is an isosceles triangle it is sufficient to prove that  $\angle AED = \angle ADE$ )

**Proof:**

Since ABCE is a cyclic quadrilateral.

$$\text{Therefore } \angle AED + \angle ABC = 180^\circ \dots\dots (1)$$

Now, CDE is a straight line.

$$\Rightarrow \angle ADE + \angle ADC = 180^\circ \dots\dots\dots (2)$$

[Since  $\angle ADC$  and  $\angle ABC$  are opposite angles of a parallelogram i.e.  $\angle ADC = \angle ABC$

From (1) and (2), we get

$$\angle AED + \angle ABC = \angle ADE + \angle ABC$$

$$\Rightarrow \angle AED = \angle ADE$$

Therefore In  $\Delta AED$ , we have

$$\angle AED = \angle ADE$$

$$\Rightarrow AD = AE.$$

In the Fig, O is the centre of the circle, prove that,  $\angle a = \angle b + \angle c$

**Solution:**

$$\angle AOB = 2\angle AEB = 2\angle AFB$$

$$\therefore \angle AOB = \angle AEB + \angle AFB$$

$$\therefore \angle a = \angle 4 + \angle 3 = 2\angle 4 \quad \dots\dots\dots (i)$$

$$\text{Now } \angle 1 = \angle 2 \quad (\text{In same segment}) \quad \dots\dots\dots (ii)$$

$$\angle b = \angle 4 + \angle 1 \quad (\text{Exterior angles equal to sum of two equal interior opposite angles})$$

$$\Rightarrow \angle b = \angle 4 + \angle 2 \quad \dots\dots\dots (iii) \text{ [from (ii)]}$$

$$\angle c = \angle 4 - \angle 2 \quad \dots\dots\dots (iv) \text{ (Since } \angle c + \angle 2 = \angle 4)$$

Adding equations (iii) and (iv) we get,

$$\angle b + \angle c = 2\angle 4 = \angle a \quad \text{[from (i)]}$$

$$\text{or } \angle a = \angle b + \angle c$$
