

Comparison of S_N2 versus S_N1 Reactions

Effect of Nucleophile

- S_N2 is a one step reaction where both the substrate and nucleophile are involved
- S_N1 is a two step reaction involving the initial formation of a planar carbocation

therefore:

S _N 1	nucleophile strength is unimportant
S _N 2	strong nucleophiles are required

Effect of Substrate

two important considerations:

- as the number of substituents on carbon increase the stability of a formed carbocation increases (therefore of lower energy)

for a S_N1 reaction 3° halides are best

- as the number of substituents increase, the bulkiness at the electrophilic carbon increases

for S_N2 reactions methyl halide is the best

S_N1 substrate $3^\circ > 2^\circ$ (1° and methyl halide do not react)

S_N2 substrate methyl halide $> 1^\circ > 2^\circ$ (3° does not react)

Effect of Leaving Group

- in both reactions the bond between the electrophilic carbon and the leaving group is broken in the rate determining step

therefore both S_N1 and S_N2 reactions require a good leaving group

weak bases that are common leaving groups

halides

sulfonate

Effect of Solvent

in the S_N1 reaction a neutral starting material is ionized to charged intermediates in the rate determining step

in the S_N2 reaction often the charge is kept constant during the rate determining step

S_N1 good ionizing solvent favored

S_N2 dependent on reaction

Comparison of E1 and E2 Reactions

Effect of Substrate

in a E1 reaction a carbocation is formed

in a E2 reaction an alkene is formed in the rate determining step
- follows Zaitsev rule where a more substituted alkene is favored

therefore for both E1 and E2 reactions the stability follows the trend:

Effect of Base

single most important factor for eliminations

if the substrate is suitable for an elimination then a
strong base will favor an E2 mechanism

a weak base will favor ionization first

therefore:

E2 strong base is required

E1 base strength is unimportant

strong bases: $\ominus\text{OH}$, $\ominus\text{OR}$, $\ominus\text{NH}_2$, $\ominus\text{CH}_3$

Orientation of Eliminations

the product with the more substituted double bond will be favored

Zaitsev rule is followed for both E1 and E2

Competition Between Substitution and Elimination

a given reaction with a haloalkane can follow four mechanisms
(S_N2 , S_N1 , E2, E1) yielding different products

trends to predict which mechanism will predominate:

- 1) weakly basic species that are good nucleophiles give predominantly substitution

examples: I^- , Br^- , Cl^- , RS^- , N_3^- , RCO_2^-

therefore 1° or 2° halides give clean S_N2

with 3° halides give predominantly S_N1 (E1 is usually minor pathway)

2) strongly basic nucleophiles give more eliminations

E2 mechanism starts to compete with S_N2 as base strength increases

- with methyl halide or 1° halides S_N2 predominates with strong base

- with 3° halides S_N2 mechanism is impossible and E2 mechanism predominates with strong base

3) sterically hindered basic nucleophiles favor eliminations

- just as elimination becomes favored with sterically hindered substrates

E2 becomes favored with sterically hindered bases

some common sterically hindered bases

potassium tert-butoxide

lithium diisopropylamide (LDA)

Factors for Substitution versus Elimination

1) base strength of the nucleophile

weak
halides, RS^- , N_3^- , CN^- , RCO_2^-
substitution more likely

strong
 HO^- , RO^- , H_2N^- , R_2N^-
elimination increases

2) steric hindrance at reacting carbon

sterically unhindered
methyl, 1°
substitution predominates

sterically hindered
branched 1° , 2° , 3°
elimination increase

3) steric hindrance of strongly basic nucleophile

sterically unhindered
 HO^- , CH_3O^- , H_2N^-
substitution may occur

sterically hindered
 $(\text{CH}_3)_3\text{CO}^-$, LDA
elimination favored

Summary of Reactivity of Haloalkanes

methyl halide

reacts only through S_N2 pathway

- no other possibility

no adjacent H's

methyl cation is too high in energy to go through S_N1 pathway

Primary Haloalkane

reactivity of R-X with nucleophiles

unhindered primary R-X

S_N2 with good nucleophiles that are not strongly basic

S_N2 with good nucleophiles that are also strongly basic but unhindered

E2 with nucleophiles that are strongly basic and hindered

no, or exceedingly slow, reaction with poor nucleophiles

Branched Primary Haloalkane

S_N2 with good nucleophiles that are not strongly basic

E2 with nucleophiles that are strongly basic (hindered or unhindered)

no reaction with poor nucleophiles

Secondary Haloalkanes

(hardest to predict)

S_N1 or $E1$ with good leaving group in polar solvent and weak nucleophile

S_N2 with good, weakly basic nucleophiles

$E2$ with strongly basic nucleophiles in polar solvent

Tertiary Haloalkanes

S_N1 and E1 with weak bases

E2 with strong base

Predicted Mechanisms by Which Haloalkanes React with Nucleophiles (or Bases)

type of haloalkane	<u>type of nucleophile (base)</u>			
	poor NUC (e.g. EtOH)	good NUC, weak base (e.g. I ⁻)	good NUC, strong, unhindered base (e.g. CH ₃ O ⁻)	good NUC, strong, hindered base (e.g. (CH ₃) ₃ CO ⁻)
methyl	no reaction	S _N 2	S _N 2	S _N 2
1°				
unhindered	no reaction	S _N 2	S _N 2	E2
branched	no reaction	S _N 2	E2	E2
2°	slow S _N 1, E1	S _N 2	E2 or S _N 2	E2
3°	S _N 1, E1	S _N 1, E1	E2	E2

Properties of Each Process

	stereochemistry	rate	rearrangements
S_N2	inversion	$k[\text{substrate}][\text{NUC}]$	never
S_N1	racemic, sometimes inversion pref.	$k[\text{substrate}]$	often, if possible
E2	anti-coplanar Zaitsev rule	$k[\text{substrate}][\text{base}]$	never
E1	Zaitsev rule	$k[\text{substrate}]$	often, if possible

Description of Electrons Control Organic Chemistry

Stability of an organic compound (or intermediate) is dependent upon the molecules ability to best fulfill the electronic demand throughout the molecule

trifluoroacetate

acetate

Ways to Stabilize Sites

we have learned a couple of ways to stabilize sites electronically

1) Resonance

- stabilizes either electron rich or electron deficient sites
- biggest factor of anything

2) Substituent Effects

- we have learned about inductive and hyperconjugation effects

for alkyl substituents: as substituents increase the electron density increases

- for electron deficient sites this is good

(therefore radicals and carbocations favor more substituents; $3^\circ > 2^\circ > 1^\circ > \text{methyl}$)

- for electron rich sites this is bad

(therefore carbanions favor less substituents; $\text{methyl} > 1^\circ > 2^\circ > 3^\circ$)

Same Considerations for Organic Reactions

organic reactions quite simply are merely species with high electron density (nucleophiles) reacting with species with low electron density (electrophiles)

the FLOW of electrons occur to stabilize the electronic charge

Nucleophilicity thus merely refers to electron density

- stronger nucleophiles have a higher electron density

Electrophiles thus merely refer to a species with a electron deficient center

- stronger electrophiles have a more electron deficient center

The only other consideration that we have dealt with is STERICS

even if the nucleophile would react with the electrophile
they need to be able to reach other spatially in order to react

now look at view of nucleophile approach
