

Class 8 Chemistry Metals and Non metals

Introduction

Introduction

In our day to day life we use many well-known materials like iron, aluminum, copper, gold, silver and many more. We are also familiar with the elements like oxygen, carbon, Sulphur as well. These are all obtained from some naturally occurring substances encompassing one or more elements or their compounds. They are termed as minerals. Minerals from which elements can be profitably extracted are termed as ores.

Fig. Ores and Minerals

- There are 92 well-known naturally occurring minerals of which 70 are metals and 20 are non-metals.
- Some metals possess the characteristics of both metals as well as non-metals. They are termed as metalloids. For instance, boron, silicon, germanium, arsenic, antimony, tellurium, and polonium.
- Elements found in free state include some metals like gold, silver, platinum etc. and some non-metals like helium, neon, argon etc. as well.
- A major proportion of metals are found in combined states like oxides, sulphides, carbonates, silicates etc. Some non-metals like sulphur, phosphorus too are found to exist in combined state.

Class 8 Chemistry Metals and Non metals

Physical properties of metal

Physical properties of metal

- Metals are solid except mercury that is found in liquid state at room temperature.

Ordinary metals Vs Mercury

- They are hard and tough except sodium and potassium that can be cut with a knife.
- They are lustrous i.e. they shine in light because metals possess free electrons that vibrates on getting in contact with light.

Shiny Metal

Fig. The key made of metal shines in light that implies metal is lustrous

- They have high melting points except caesium and gallium have very low melting point.
- They are good conductors of heat and electricity. The best conductors of electricity are silver and copper whereas lead and mercury are comparatively poor conductors.

Fig. Metal is used at the tip of the plug that is inserted into the socket

- They have high density except alkali metals like lithium, sodium and potassium.
- They are **malleable**. they can be beaten into thin sheets. For instance, the aluminium foil we use to pack food is manufactured by beating the aluminium metal into thin sheets. This a characteristic property of metal.

Fig. Aluminium is beaten into thin sheets to make aluminium foil used to pack food

- They are **ductile**. they can be drawn into wires. For instance. We all are familiar with copper and aluminium wires. It is due to their characteristic property of ductility that these metals can be drawn into wires.

Fig. copper aluminium are drawn into wires

- They are **sonorous**. they produce a ringing sound when struck against a hard object. For instance, your school bells are made of metal that produces a ringing sound after the period is over when struck hard by a hammer.

Fig. bells in temples are made of metal that when struck against hard surface produces sound

Examples are iron, gold, silver, magnesium, copper, aluminium and many more

Class 8 Chemistry Metals and Non metals

Physical properties of non-metals

Physical properties of non-metals

- Non-metals may be either solids, liquids or gases.
- Solid non-metals are brittle and break down into powdery mass on striking with a hammer except diamond which is the hardest non-metal.
- They have a dull luster but iodine is lustrous.
- They have low melting points except diamond that has very high melting point.
- They are poor conductors of heat and electricity except graphite.
- They are not malleable.
- They are not ductile.
- They are not sonorous.
- Examples are carbon, Sulphur, oxygen, phosphorous and many more.

Fig. Bonding of non-metallic elements

Reactions of metal with water

- Sodium being very reactive reacts vigorously with water leading to the production of sodium hydroxide and hydrogen. Therefore it is stored in kerosene.

- Magnesium undergoes reaction with water to form magnesium hydroxide and hydrogen.

- Whereas iron reacts very slowly with water.

Class 8 Chemistry Metals and Non metals

Reactions of metal with acids

Reactions of metal with acids

Metals react with acids to produce hydrogen gas. If a matchstick is brought near the mouth of the tube containing the product of the reaction then we hear a pop sound. It is this hydrogen gas that burns with a pop sound.

- For instance, Magnesium reacts with dilute hydrochloric acid to form magnesium chloride and hydrogen.

- Copper does not react with hydrochloric acid but reacts with sulphuric acid.

Class 8 Chemistry Metals and Non metals

Reactions of metal with bases

Reactions of metal with bases

Metals react with sodium hydroxide to produce hydrogen gas.

- For instance, zinc reacts with sodium hydroxide to give sodium zincate.

Class 8 Chemistry Metals and Non metals

Reactions of non-metal with oxygen

Reactions of non-metal with oxygen

Non-metals react with oxygen to produce non-metallic oxides that are acidic in nature because when dissolved in water non-metallic oxides give off non-metallic acids.

- Sulphur reacts with oxygen producing sulphur dioxide which on further reaction with water gives sulphurous acid.

Class 8 Chemistry Metals and Non metals

Reactions of non-metal with water

Reactions of non-metal with water

Non-metals do not react with water but are very reactive in air due to which they are stored in water. Phosphorous is a vigorously reacting non-metal that catches fire if exposed to air. To avoid such reaction phosphorous is stored in water that cuts off its contact with atmospheric oxygen.

Class 8 Chemistry Metals and Non metals

Reactions of non-metal with acids

Reactions of non-metal with acids

Non-metals do not react with acids. This is due to the fact that a substance undergoing reaction with acids, donates electrons to the H⁺ ions produced by the acids. But non-metals are acceptor of electrons and hence they do not donate electron to the hydrogen ion of the acid. As a result they do not react with dilute acids. But there are some exceptions.

Class 8 Chemistry Metals and Non metals

Reactions of non-metal with bases

Reactions of non-metal with bases

Reactions of non-metals with bases are quite complex. They react with bases to form salt.

- Reaction of calcium hydroxide and chlorines gives bleaching powder.

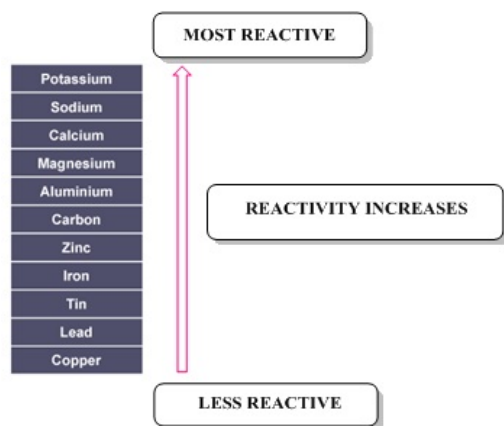

Class 8 Chemistry Metals and Non metals

Displacement reaction in metals

Displacement reaction in metals

In displacement reaction a more reactive metal displaces a less reactive metal but a less reactive metal cannot displace a more reactive metal.

Let us take 5 beakers.

- In beaker A Zn being more reactive than copper replaces copper from the solution of copper sulphate and forms zinc sulphate.

- In beaker B iron being more reactive than copper replaces it from its solution and forms iron sulphate.

- In beaker C there would be no reaction as less reactive metal (copper) cannot displace more reactive metal (zinc) from its solution.
- In beaker D there would be no reaction as less reactive metal (copper) cannot displace more reactive metal (iron) from its solution.
- In beaker E there would be no reaction as less reactive metal (iron) cannot displace more reactive metal (zinc) from its solution.

Class 8 Chemistry Metals and Non metals

Uses of metals

Uses of metals

- Metals being hard, tough are used in manufacturing automobiles, machinery, trains, satellites, aeroplanes, industrial gadgets.

- Due to its characteristic of being a good conductor of electricity and ductility it is used in making wires, electrical appliances, circuits and many more.

- Being a good conductor of heat it is used in making utensils, water boilers.

Class 8 Chemistry Metals and Non metals

Uses of non-metals

Uses of non-metals

- Non-metal is the basic requirement of life. Oxygen is inhaled while breathing.
- Nitrogen is used in fertilizers to enhance the fertility of soil.
- Chlorine and fluorine are used for water purification.
- It is used as an antiseptic and applied on wounds.
- It is used as disinfectant.
- It is used in crackers.
